(54) Lubricating greases.

(55) The invention provides the use of a compound selected from:

(a) fluorinated bis-benzimidazoles of the formula:

wherein R is -F or -CH3; p and q are integers such as the sum p + q is from 0.1 to 2;

(b) esters of phosphorous acid with a perfluoroalkoxyalcohol;

(c) perfluoropolyethers with phosphinic groups at one or both ends;

(d) perfluoropolyethers with perfluoropolyoxypentafluoro-alkyl-substituted phosphotriazinic groups;

as anti-wear additives for a lubricating oil based on polytetrafluoroethylene (PTFE) in the form of fine particles and on a liquid dispersant selected from an oligomer of trifluoro-chloroethylene or from a perfluoropolyether.

EP 0 605 403 A2

This invention relates to a process for preparing lubricating greases, particularly lubricating greases based on polytetrafluoroethylene and perfluoropolyethers.

As is known, the most common and general method of preparing greases consists in suspending a thickening filler in a liquid or waxy dispersing medium.

In particular, when the thickening filler does not consist of a soap (such as for example the derivatives of lithium, sodium, or calcium of fatty acids), or at any rate of a compound capable of forming a colloidal solution or a suspension stable in the dispersing liquid, the grease tends to show a lack of stability with the passing of time and to lose its original lubricating properties as well as, at worst, to suffer a separation of the oil during ageing (separation of oil as defined by the IP 121/75 and FTMS 791-321 standards), with the ensuing deterioration of the rheological and tribological properties.

It is known that a fluorinated grease may be formulated (see for example J. Messina, J. Am. Soc. of Lubr. Eng. (Dec. 1969) 475-481, and Italian Patent No. 963 579) by suspending a polytetrafluoroethylene telomer having an average molecular weight of 20,000 - 30,000 and partially chlorinated chain terminals (as a result of the radical polymerization method in suspension of 1,1,2-trichlorotrifluoroethane) in a perfluorinated liquid, such as for example the perfluoropolyethers described in Italian Patent Nos. 792 673 and 790 651.

The above perfluoropolyethers have the commercial name Fomblin Y and the general formula

and respectively Fomblin Z having the general formula

in which the oxyperfluoroalkylene units are statistically distributed along the chain, wherein in formula (I) X and Y are a terminal $-CF_3$ or $-C_2F_5$ group, and m and n are integers the sum of which ranges from 10 to 100 and the m/n ratio ranges from 10 to 50; and in formula (II) A and B are terminal $-CF_3$, $-C_2F_5$, $-CF_2Cl$, or $-CF_2CF_2Cl$ groups, and p and q are integers the sum of which ranges from 10 to 200 and the p/q ratio ranges from 0.1 to 10.

Also useful for the same purpose are the perfluoropolyethers of the general formula

wherein the terminal groups A and B are the same as those of the formula (II); t is an integer greater than or equal to 3; and r, s, t are integers the sum of which ranges from 10 to 3000 and the

ratio has a value ranging from 0.01 to 0.3 and the r/s ratio has a value ranging from 0.1 to 10.

The products of formula (III) may be obtained by reacting a perfluorinated olefin on a perfluoropolyether containing peroxide groups, in the presence of U.V. radiation.

These products and the preparation thereof are described in Italian Patent Application No. 20270 A/82 filed by the present Applicants.

The polytetrafluoroethylene telomer defined hereinbefore is usually obtained as a 7% suspension in 1,1,2-trichlorotrifluoroethane in which the average diameter of the particles of the telomer is less than 30 microns.

The known formulation method consisted in gradually adding the perfluoropolyether to the 7% polytetrafluoroethylene suspension, or to a partially concentrated suspension at 50-60%, by simultaneously evaporating the solvent under vacuum.

The resulting grease exhibits good lubricating properties; however, the process is very long and complex. In particular, the preparation of an amount of about 30 kg of grease involves the mixing of a volume up to about 50 liters of telomer suspension with the dispersing liquid; it is therefore necessary to evaporate from the mixture up to about 45 liters of solvent, which, since it is miscible in perfluoropolyether, tends to leave in the final grease a small amount of non-evaporable residue which is harmful as regards both the stability of the grease and the evaporation at high temperature or under vacuum. Usually, the solvent evaporation step takes from 20 to 45 hours.

Furthermore it is not possible to readily increase the scale of each preparation owing to the difficulty due to the heat and mass exchange in too great volumes. Moreover, both the high-temperature evaporating properties and thermal stability properties of the grease are adversely affected by the relatively low thermal stability of the telomer, owing to the presence of chlorinated chain terminal groups. It is known in fact that the C-Cl bond is less stable than the C-F bond.

The thermal stability of the telomer is lower than that of the Fomblin liquid; as a consequence the improved thermal resistance properties obtained by employing Fomblin instead of other suspending fluids are partially lost.

It was previously known that the best performances of a polytetrafluoroethylene as a thickening agent for a liquid in order to provide a grease corresponded to the described telomer (Journal ASLE 1989, 12, page 475, J. Messina).

The present invention relates to a new process for preparing lubricating greases in which, as an essential ingredient, polytetrafluoroethylene having a molecular weight not below 50,000 and a high thermal stability is employed in the form of particles in suspension in a perfluorinated liquid of the type of perfluoropolyethers described hereinbefore or of the type of oligomers of trifluorochloroethylene having a viscosity ranging from 100 to 1,000 cst at 20 °C.

It is known to obtain, by polymerization of tetrafluoroethylene in an aqueous dispersion with the use of ammonium persulphate and a Mohr salt, a polymer having a molecular weight ranging from 500,000 to 1,000,000. The particles of such a polymer, after separation from the dispersing medium, are found to consist of aggregates with sizes ranging from 1 to 200 microns, such aggregates consisting of primary particles with sizes ranging from 0.05 to 0.5 microns, which have either a spherical shape or the shape of a rounded rod with the major axis below 0.5 microns. The particles have a surface area of from 5 to 15 m²/g.

The present invention provides a process for preparing a lubricating grease based on polytetrafluoroethylene and on a liquid dispersant selected from oligomers of trifluorochloroethylene or from perfluoropolyethers of the classes of general formula

wherein:

X and Y are a terminal -CF₃ or -C₂F₅ group;

m and n are integers, and m + n = 10-100, and m/n = 10-50;

A and B are terminal -CF₃, -C₂F₅, -CF₂Cl or -CF₂CF₂Cl groups;

p and q are integers, and p + q = 10-200, and p/q = 0.1-10;

r, s and u are integers, and r + s + u = 10-3000,

40

$$\frac{u}{r+s} = 0.01-0.3,$$

and r/s = 0.1-10; and t ≥ 3;

45 characterized in that polytetrafluoroethylene having a molecular weight in the range of from 500,000 to 1,000,000, comprising particles of the aggregated type, previously heated under vacuum to remove volatile products which may be contained therein, is mixed, under reduced pressure and at a temperature higher than room temperature, with an oligomer of CF₂CFCl having a viscosity, at 20 °C, from 100 to 1000 cst, or with a perfluoropolyether selected from the classes (I), (II) or (III) and having a viscosity, at 20 °C, from 20 to 50 4000 cs if belonging to class (I), from 40 to 6000 cs if belonging to class (II), and from 40 to 30,000 cs if belonging to class (III), and also with a perfluorinated surfactant of the anionic type, characterized by a perfluoroalkylene chain or by a perfluoroxyalkylene chain, the amount of polytetrafluoroethylene being from 15% to 40% by weight of the total mix, the amount of perfluoropolyether or of oligomer of CF₂CFCl being from 60% to 85% by weight of the total mix, and the amount of surfactant being from 0.1% to 0.4% by weight of the polytetrafluoroethylene.

55 It has now been found that it is possible to attain the disaggregation of the aggregated particles of polytetrafluoroethylene into primary particles having sizes ranging from 0.05 to 0.5 microns of rounded or spherical shape, when the aggregated particles are soaked or suspended in a perfluorinated liquid selected

EP 0 605 403 A2

from: perfluoropolyether of the Fomblin Y type of formula (I) having a kinematic viscosity of from 20 to 4000 cst at 20°C, preferably from 40 to 1600 cst at 20°C, or of the Fomblin Z type of formula (II) having a viscosity of from 40 to 6000 cst at 20°C, preferably from 50 to 6000 cst at 20°C, more preferably from 60 to 6000 cst at 20°C, or a perfluoropolyether of formula (III) having a kinematic viscosity of from 40 to 30,000 cst at 20°C, preferably from 60 to 28,000 cst, or an oligomer of trifluorochloroethylene having a kinematic viscosity of from 100 to 1000 cst, and then the aggregated particles of polytetrafluoroethylene suspended in the Fomblin liquid are subjected to a grinding or disaggregating process in a refiner, thus directly obtaining the grease having the final rheological and mechanical properties as desired.

In particular, the soaking and suspending process of the polytetrafluoroethylene particles of the aggregated type having sizes from 1 micron up to 200 microns, and consisting of aggregations of spherical or rounded rod-like particles of submicronic sizes, may be accomplished as follows:

- (1) The inner voids of the polytetrafluoroethylene particles are evacuated from air and condensed vapours (e.g. water vapours) by means of heating for about 2 hours at 50°C under a vacuum of the order of 10^{-1} - 10^{-3} torr.
- (2) The particles so treated are subjected to a soaking and suspending treatment, at a temperature higher than the room temperature and under reduced pressure, with a perfluoropolyether liquid such as Fomblin Y or Z or of formula (III), or with a CF₂CFCI oligomer as defined hereinbefore, which has previously been deaerated. The perfluoropolyether liquid possesses a high air-solubilizing power, up to 20% by volume at 20°C and at atmospheric pressure. Polytetrafluoroethylene is employed in amounts of from 15 to 40% by weight, preferably from 18 to 35% by weight, calculated on the basis of the total mix.
- (3) The perfluoropolyether or the CF₂CFCI oligomer, used in an amount of from 60 to 85% by weight, preferably from 65 to 82% by weight, referred to the total mix, is added with a perfluorinated surface-active agent of the anionic type having a perfluoroalkylene chain, of general formula

wherein n is an integer from 2 to 12, preferably from 3 to 8, more preferably from 3 to 7, and D is selected from the groups -COOM, -SO₃M and -OC₂F₅SO₃M where M is a cation selected from Na, K, 30 1/2Ba and 1/2Ca, or with a surface-active agent of the polyoxyperfluorinated anionic type of general formula

35 wherein R is either like or unlike Q and is selected from CF₃- and MOCOCF₂- in which M is a cation as defined hereinabove, and Q is a -CF₂COOM group where M is a cation as defined hereinabove, provided that when R is the same as Q, i is equal to zero; oxyperfluoroalkylene units C₂F₄O, C₃F₆O and CF₂O are statistically distributed along the chain, provided that the C₃F₆O and C₂F₄O units are not present contemporaneously; i and k are equal to zero or are integers from 1 to 7, preferably from 1 to 4, h is an 40 integer from 1 to 7, and the sum of i, k and h is an integer from 2 to 10, preferably from 2 to 6.

The surface-active agent is employed in amounts of from 0.1% to 0.4%, preferably from 0.2 to 0.3%, by weight, in respect of the polytetrafluoroethylene powder.

Some examples of surface-active agents which have provided excellent results are the following:

10 NaOOC-CF₂O-(C₂F₄O)₂-(CF₂O)₂ - CF₂COONa .

The soaking of polytetrafluoroethylene of the described type with perfluoropolyether liquid leads to a very viscous pasty suspension. Such suspension is subjected to disaggregation or grinding of the aggregated particles into primary particles by treatment in a refiner such as a triple roll mill, for example of the type manufactured by Officine Meccaniche Molteni, Italy.

15 Such a machine consists of three parallel rolls cooled by inside circulation of water and adjustable as to revolving speed and gap between the rolls; the adjacent rolls revolve in opposite directions to each other and at different speeds; furthermore they may be put into contact with each other so as to exert a pressure, while the pressure exerted on the suspension of polytetrafluoroethylene in perfluoropolyether may be hydraulically regulated at from 1 to 50 atmospheres by a control servofluid.

20 The suspension is introduced between the first roll revolving at low speed and the second roll which revolves at an intermediate speed, and is then extracted after having passed between the second roll and the third roll, which revolves at a higher speed.

25 It has been found that under the best operational conditions it is necessary that the hydraulic control pressure of the servofluid be from 10 to 75 atmospheres, preferably from 15 to 65 atmospheres, that the speed of the first roll be from 20 to 50 rpm, the speed of the second roll from 60 to 140 rpm, and the speed of the third roll from 150 to 400 rpm.

30 In particular, the action of total disaggregation of the particles aggregated to primary particles having a spherical shape or the shape of a rounded rod is obtained when the particles of polytetrafluoroethylene powder are fully degassed and the perfluoropolyether liquid has completely wetted all the voids and the gaps formed among the primary particles in the inside of the aggregated particles.

35 The action of full wetting and soaking of the polytetrafluoroethylene particles having a surface tension of 19-22 dynes/cm is made possible by the low value (17.5-21 dynes/cm) of the surface tension of the perfluoropolyether.

30 The pressure between the cylinders is hydraulically transmitted homogeneously through the suspension, without formation of any air bubbles due to coalescence among microbubbles, the forming of which could detach the liquid film adhering to the particles or to the rolls, thereby causing sintering phenomena among the particles with formation of new irregular and fibrous aggregates and breaking phenomena of the primary particles.

40 The particles disaggregate owing to the friction therebetween and with the perfluoropolyether fluid threads adhering to the walls of the revolving rolls or to the other particles.

In order to obtain a disaggregation of the aggregated particles to primary particles without causing a microrupture of the primary particles or the reaggregation or sintering of the particles into fibrous or irregular aggregates, it is necessary to prevent the unwetted particles from coming directly into contact with one another or with the unwetted rolls.

45 The duration of the adherence of the liquid film to the particles and to the rolls depends, besides on the absence of gases and vapours in the suspension, on the mechanical resistance characteristics of the fluid film adhering to the particles and to the rolls.

Such stabilities of the grease, namely the adherence duration and the mechanical resistance of the liquid adhering to the particles, is improved by the presence of suitable agents having surface activity which probably act as wetting agents, thus increasing the adhesion of the liquid film to the surface.

Such resistance depends besides on the surface tension also on the molecular weight and by consequence on the viscosity of the fluid and on the chemical structure thereof.

50 The perfluoropolyether fluids possess a high mechanical resistance, as is proved by measurements with the 4-ball Shell test under EP conditions (test IP 239, where welding load values ranging from 400 to 500 kg, corresponding to values higher than the average values of the other added fluids, are measured).

On the other hand it may be ascertained how, by using a fluorinated fluid, characterized by a low surface tension (19 dynes/cm) and by a low molecular weight, such as 1,1,2-trichlorotrifluoroethane, as a

suspending liquid for the soaking and the disaggregation of polytetrafluoroethylene, it is impossible to obtain a homogeneous disaggregation of the polytetrafluoroethylene powder into primary particles. In fact such liquid does not possess sufficient viscosity and mechanical resistance properties to bring about the protecting action on the particles and to avoid the aggregation and sintering thereof to fibrous particles.

5 To obtain the desired protecting action, the perfluoropolyether or the CF₂CFCI oligomer must possess a viscosity higher than 10 cs at 20°C, preferably higher than 30 cs at 20°C, as already mentioned hereinbefore.

Furthermore, the mechanical stability of the grease, its wear resistance also when it operates under great loads, and its capability of imparting corrosion resistance to the materials on which it is applied, may 10 be enhanced by the presence of suitable additives such as fluorinated bis-benzimidazoles having the structure :

20 wherein R may be F, CF₃; p and q are integers, and the sum p+q = 10-100, and the p/q ratio = 0.1-2; or such as
the esters of phosphorous acid

30 or the phosphines such as

wherein C₆H₄ is a disubstituted phenyl residue which is bound to trivalent phosphorus. Also suitable are perfluoropolyethers having, at both ends, aryl-substituted phosphonic groups, or phospho-triazinic groups
40

45

50

where Rf is a perfluoroalkyl radical or a polyoxyperfluoroalkyl radical, and Ar is an aryl radical.

If the fluids are added by 0.2-1% by weight of the wear-resisting and corrosion-resisting additives specified hereinabove, their mechanical resistance is improved to such an extent that the welding load with the 4-ball Shell test rises to values of 600-800 kg; furthermore, the corrosion resistance of the metal lubricated and subjected to oxidizing atm sphere conditions improves also.
55

The tests which permit the obtaining of a grease having satisfactory physical, mechanical, rheological and wear-resisting properties to be ascertained are :

- examination under an optical microscope to ascertain the disappearance of the aggregates and the absence of fibrous aggregates;
 - examination under the electron microscop to determin both the shape and the particl size distribution of the primary particles;
 - 5 - consistency of the grease determined through penetration measurements according to test ASTM D 1403 on the grease as such, handling after the Roll test (ASTM D 1831, at 100 °C);
 - per cent separation of oil at 100 °C (method FTMS 791-321) or at 40 °C under load (method IP 121/75);
 - 10 - mean diameter of the trace left by the wear and wear load under the 4-ball Shell apparatus (tests ASTM D 2266, IP 239);
 - loss of oil under evaporation and vapour tension at different temperatures (Knudsen method).
- The applicative importance of the grease is found in the following fields :
- lubrication under high loads and under severe chemical and physical conditions where high mechan-ical, thermal and chemical resistances are required;
 - 15 - under vacuum, where a high stability to evaporation, i.e. an extremely low vapour tension and a high lubricating power, are required;
 - where a high resistance to electromagnetic radiations (γ , X, ultraviolet and Laser rays) and to accelerated particles (electrons, protons and ions) is required.
- Such applications are possible particularly due to the combination of perfluoropolyether and poly-
- 20 tetrafluoroethylene, in which the C-Cl and C-H bonds of low stability are either absent or extremely few and the C-O and C-F bonds are predominant.

The invention will be further described with reference to the following illustrative Examples.

EXAMPLE 1

- 25 7 kg of crystalline polytetrafluoroethylene having a molecular weight of about 600,000, prepared by polymerization in an aqueous dispersion at 60 °C and 20 atm. by means of ammonium persulphate and Mohr salt, consisting of aggregated particles having diameters ranging from 1 to 100 microns as determined under an optical microscope, were introduced into a mechanical mixer equipped with Z-shaped arms, a
- 30 mechanical seal cover with connections for vacuum and for the introduction of liquids as well as for the under vacuum removal of gases and vapours, and with a thermoregulating jacket.
- The jacket was thermoregulated at a temperature of 50 °C while the vacuum-connection of the mixer was connected with a mechanical vacuum pump, whereupon vacuum was created up to a residual pressure of $5 \cdot 10^{-2}$ torr, and such vacuum was maintained for 3 hours.
- 35 Into a cylindrical steel tank having a capacity of 20 l, resistant to vacuum and equipped with connections for vacuum and with a heating jacket, there were introduced 16.4 kg (8.6 l) of perfluoropolyethereal oil Fomblin Y produced by Montedison S.p.A., having a kinematic viscosity of 1500 cs (at 20 °C), and additioned with 14 kg of a surfactant having the formula $CF_3(CF_2)_6COONa$.
- The oil was heated to 50 °C and the tank was connected with the mechanical vacuum pump, thus creating
- 40 in the tank interior a vacuum corresponding to a final residual pressure of $5 \cdot 10^{-2}$ torr for 3 hours. In this way the polytetrafluoroethylene powder and the Fomblin oil were completely freed from gases and volatile vapours.
- Successively the arms of the mixer were rotated and, by gravity, the Fomblin liquid was gradually introduced, over a time-period of 30 minutes, into the mixer. Then, heating of the mixer jacket was stopped
- 45 while continuing stirring the mass for 3 hours until complete cooling to 20 °C; at the end a pasty suspension was obtained.
- On a suspension sample, on a Brookfield rotary viscosimeter, a viscosity of 185,000 cp at 20 °C was determined. The suspension was discharged from the mixer and subjected to thickening in a refiner equipped with three rolls of 180 mm diameter, the roll length being 400 mm, by causing the suspension to
- 50 pass between the rolls revolving at a speed of 40 rpm and of 70 rpm, and then by collecting it through detachment from the surface of the third roll revolving at 150 rpm. The rolls were kept in contact by means of a pressure of the servofluid of about 60 atm. The 23.4 kg of pasty suspension were made to pass between the three rolls in a time-period of 2 hours.
- A film consisting of grease thus formed, which was continuously detached from the third roll by means of a
- 55 steel scraping blade.
- A greas sampl was drawn and the consistency thereof was measured by a penetration determination according to th ASTM D 1403 method (half scale) at a temperature of 25 °C. A value of 245 (mm/10) was found.

EP 0 605 403 A2

The grease was made to pass another four times between the rolls kept at the same speed and at the same distance from one another, thus obtaining, in order, the following penetration values as a consistency measure :

5	after the 1st run	245 mm/10 of penetration
	after the 2nd run	242 " "
	after the 3rd run	240 " "
10	after the 4th run	240 " "

The succession of values shows that on the 4th passage a mechanically stable grease was obtained. A sample of the grease was placed into the cup of a penetration measuring apparatus (ASTM D 1403 test) and was subjected to a manual handling, the so-called 60-stroke working; the grease so treated exhibited a penetration of 241 (mm/10).

15 A grease sample subjected to the 10,000-stroke mechanical test exhibited a penetration, according to ASTM D 1403, of 250 (mm/10), which indicated a high mechanical stability. On the basis of such penetration values, this grease may be classified at the 3rd degree of consistency according to the classification of the National Lubricating Grease Institute (NLGI). On a sample of the grease, the thickening agent was recovered by means of repeated washings with 1,1,2-trichlorotrifluoroethane and by decantation in order to remove the Fomblin oil. The solid polytetrafluoroethylene, examined under an optical microscope, did not reveal particles having sizes greater than one micron.

20 The powder thus recovered was examined under an electron microscope in order to determine both shape and granulometric distribution of the primary particles.

25 The diameters of the particles varied from 0.13 microns (2% fraction) to 0.35 microns (0.5% fraction), the average diameter value being 0.19 microns.

The contour of the particles was round-shaped.

Samples of grease were subjected to the following measurements :

- Oil separation, IP 121/75 method (40°C , 168 hours) + 3.9%
- Oil separation, FTMS 791-321 method (100°C , 30 hours) + 5%
- Consistency (ASTM D 1403, $\frac{1}{2}$ scale, at 25°C) after the Roll test (ASTM D 1831, at 100°C):
- penetration after 4 hours: + 0.5% variation
- penetration after 8 hours: + 3.8% variation
- Diameter of the trace left by wear on a 4-ball Shell machine (ASTM D 2266):
- mean \varnothing of the trace left by wear at 50°C : 1.45 mm
- mean \varnothing of the trace left by wear at 120°C : 1.55 mm
- Wearing load on a 4-ball Shell machine (IP 239 method, spindle speed = 1460 rpm): 580 kg
- Evaporation (ASTM D 972): weight loss at 149°C after 22 hours: 0.01%
- Vapour tension (at 20°C) : 2.10^{-12}
- Pour point temperature : -30 °C .

In order to establish the sealing properties of the grease under high vacuum and at low temperature, the following test was carried out.

Onto a Pyrex Schott glass flask (A) of 1 l capacity, having a ground-glass conical neck with an inner diameter of 26 mm, a vacuum cock (B) with a double ground-glass cone having an outer diameter of 26 mm was mounted, and on this cock a 3-way coupling (C) with a ground-glass cone of 26 mm inner diameter was fitted for connection with cock (B), as well as a ground-glass cone of 12 mm diameter to which a ionization vacuum feeler and a vacuum cock (D) were connected, the latter being connected with a vacuum system equipped with a vacuum diffusion pump. The volume comprised between cocks B and D was 50 cm³.

50 All ground-glass surfaces were lubricated with the grease prepared according to Example 1, the apparatus was mounted, cocks B and C were kept open, and the whole was connected with a vacuum system; after 30 minutes, a vacuum corresponding to a residual pressure in the system A-B of 2.10^{-8} torr, as read on a gauge inserted in coupling C, was attained.

Vacuum cock D was closed and after 24 hours it was checked to ascertain that the vacuum in system A-B had not changed.

55 Vacuum cock B was closed and disconnect d from coupling C, and section A-B was placed in a freezer regulated at -25 °C, keeping it there for 24 hours. After this period, section A-B was removed from the freezer, and flask A was manually rotated 20 times with respect to coupling B in a total time of 5 minutes,

leaving cock B closed.

Coupling C was then connected with cock B and vacuum was created again in connection B-C without opening cock D, until a final residual pressure of 2.10^{-8} torr was attained. Cock D was closed in order to cut off the suction to the pump, cock B was opened and it was ascertained that the pressure in system A-B was 3.10^{-8} torr.

Such test proved the perfect sealing power of the grease when used to lubricate vacuum flanges, even after slipping of the sealing surfaces at a low temperature of -25°C .

The test was repeated, but using a commercial grease based on polytetrafluoroethylene and mineral wax having a softening point of $45\text{--}47^{\circ}\text{C}$; after freezing of system A-B in the freezer at -25°C for 24 hours, flask

10 A could not be rotated with respect to coupling B.

A grease sample was subjected to a resistance test to aviation fuel oil, according to MIL G 27617 standard (fuel oil according to ML S 3136 standard), by determining the solubility in fuel oil after stirring of the grease in fuel oil for 30 minutes at 25°C , and the resistance of the grease smeared on aluminium strips immersed in fuel oil for 8 hours at 70°C .

15 It was thus ascertained that the grease was insoluble in fuel oil and protected the metal strip from any corrosive action or any alteration.

COMPARATIVE EXAMPLE 1

20 The same apparatus described in Example 1 was used.

7 kg of polytetrafluoroethylene in the form of powder of the same quality and with the same characteristics as the product described in Example 1 were introduced into the previously described mixer equipped with Z-shaped arms.

Onto the powder there were poured, in 30 minutes, 8.6 l of Fomblin Y liquid having a kinematic viscosity of

25 1500 cs at 20°C and addition with a surfactant of formula $\text{CF}_3(\text{CF}_2)_6\text{COONa}$ heated to a temperature of 50°C ; the whole was stirred for a further 3 hours, whereupon it was allowed to cool down spontaneously.

A pasty suspension was obtained which, on the Brookfield rotary viscosimeter, exhibited a viscosity of 100,000 cp at 20°C .

This suspension was conveyed to processing in the triple roll mill described in Example 1 and was

30 subjected to four runs, the pressure between the rolls being adjusted to 30 atm.; each run lasted 2 hours, until a constant consistency was attained.

The penetration degrees attained (ASTM D 1403, $\frac{1}{2}$ scale, at 25°C) were as follows:

35

after the 1st run	288 (mm/10)
after the 2nd run	285 (mm/10)
after the 3rd run	284 (mm/10)
after the 4th run	284 (mm/10)

40

On the grease manually handled with 60 strokes, a penetration of 310 (mm/10) was determined, while on the grease mechanically treated, a penetration of 340 (mm/10) was determined after 10,000 strokes, which revealed a low mechanical stability.

These penetration values put the grease in the 1-2 degree of consistency according to the NLGI classification. Samples of this grease were subjected to the following measurements:

45

- Oil separation, method IP 121/75 (40°C , 168 hours) 6.5%
- Oil separation, method FTMS 791-321 (100°C , 30 hours) 9.5%
- Consistency (ASTM D 1403, $\frac{1}{2}$ scale, 25°C) after the Roll test (ASTM D 1831, 100°C):
 - penetration after 4 hours + 4% variation
 - penetration after 8 hours + 9% variation

50

- Diameter of the traces left by wear tested on the 4-ball Shell machine (ASTM D 2266):
 - mean \varnothing of the trace left by wear at 50°C : 2.5 mm
 - mean \varnothing of the trace left by wear at 120°C : 2.8 mm.

The obtained data, when compared with those of the grease of Example 1, show the importance of the removal of air from the voids of the polytetrafluoroethylene powder and of the degassing of Fomblin with a view to ensuring good rheological properties as well as a high intrinsic and mechanical stability of the grease.

COMPARATIVE EXAMPLE 2

The same apparatus as described in Example 1 was used. 7 kg of polytetrafluoroethylene of the same quality and characteristics as the product described in Example 1 were introduced into the mixer equipped with Z-shaped arms and were degassed under a vacuum of 5.10^{-2} torr. 8.6 l of trichlorotrifluoroethane ($CF_2Cl-CFCl_2$), degassed from the air at incipient boiling temperature ($47^\circ C$), were then added, maintaining the mass under stirring inside the arm-mixer. Stirring was carried on for a further 3 hours, until the mass had cooled down to $20^\circ C$.

The suspension was treated on the triple roll mill for 4 hours, and 4 runs were carried out in succession, each run having a duration of 4 hours, as described in Example 1.

A suspension was thus obtained and the solvent floating on the polytetrafluoroethylene powder was separated. In a sample of such suspension, examined under the optical microscope, the particles appeared to be organized in irregularly shaped aggregates of the dendritic type, with particle sizes ranging from 0.5-1 to 100-200 microns, which indicates an irregular grinding effect and a re-aggregation of the starting powder.

The suspension was put again into the Z-arm-mixer and was maintained under stirring, while the jacket was thermo-regulated at $50^\circ C$. From the 20-liter tank containing 8.6 l of Fomblin having a viscosity of 1500 cs ($20^\circ C$) and additioned with a surfactant of formula $CF_3(CF_2)_6COONa$, Fomblin was introduced into the mixer in a time-period of 4 hours, while most of the trichlorotrifluoroethane solvent was simultaneously distilled.

Stirring was continued for a further 3 hours at $50^\circ C$, keeping the mass under a vacuum of 50 torr and lastly of 0.1 torr, finally allowing the mass to gradually cool down under stirring.

A grease having a fibrous appearance was obtained, which was conveyed to the triple roll mill, where it was subjected to 4 runs, each run lasting 2 hours.

A grease having a fibrous appearance was obtained again, which exhibited a penetration (ASTM D 1403) of 200 (mm/10), and which, after a manual 60-stroke working, became 220 (mm/10) and, after a mechanical 10,000-stroke processing, became 275 (mm/10).

Samples of the grease were subjected to the following measurements :

- Oil separation, method IP 121/75 ($40^\circ C$, 188 hours) 9%
- Oil separation, method FTMS 791-321 ($100^\circ C$, 30 hours) 11%
- Consistency (ASTM D 1403, $\frac{1}{2}$ scale, $25^\circ C$) after the Roll test (ASTM D 1831, $100^\circ C$) :
 - penetration after 4 hours + 7% variation
 - penetration after 8 hours + 8% variation
- Diameter of the traces left by wear on the 4-ball Shell machine (ASTM D 2266) :
 - mean ϕ at $50^\circ C$ 2.3 mm
 - mean ϕ at $120^\circ C$ 3.5 mm
- Evaporation (ASTM D 972) at $149^\circ C$, 22 hours: - 2%

The properties given show that the grease prepared according to Comparative Example 2 possessed neither satisfactory properties of intrinsic and mechanical stability, nor satisfactory rheological properties as compared to those of the grease prepared according to Example 1.

This is ascribable to the inadequate suspending and protective action of 1,1,2-trichlorotrifluoroethane during the grinding and disaggregation process of polytetrafluoroethylene.

The poorer stability to evaporation of the grease at $149^\circ C$ is ascribable to the persistence of trichlorotrifluoroethane in the grease after formulation.

EXAMPLE 2

The same apparatus as described in Example 1 was used. 7 kg of polytetrafluoroethylene of the same type as that described in Example 1 were introduced into the mixer, were degassed at $50^\circ C$ under a vacuum of 5.10^{-2} torr and additioned with 9 liters of perfluorinated polyether Fomblin Z having a viscosity of 250 cs (at $20^\circ C$) and further additioned with 14 kg of a surfactant of formula :

previously deaerated at $50^\circ C$ under a vacuum of 4.10^{-5} torr. The suspension was homogenized by stirring for 3 hours while the temperature was allowed to drop to $20^\circ C$; a pasty suspension was thus obtained, which was worked on the triple roll mill by passing it 4 times between the rolls, each run taking 2 hours, the rolls being maintained in contact with one another under a servofluid pressur of 30 atm.

After each run, the following penetration values (ASTM D 1403, $\frac{1}{2}$ scale) were obtained :

5

after th	1st run	240 mm/10
after th	2nd run	235 mm/10
after the	3rd run	231 mm/10
after the	4th run	231 mm/10

On a sample of this grease, after a mechanical 10,000-stroke working, a penetration of 235 (mm/10), corresponding to a high mechanical stability, was measured.

10 On a grease sample, after separation of the oil by means of 1,1,2-trifluorotrichloroethane, the particles of the thickening polytetrafluoroethylene were examined under a transmission electron microscope, whereby a particle size distribution ranging from 0.1 to 0.4 microns was determined. The shape of the particles appeared rounded. Samples of this grease were subjected to the following measurements :

- Oil separation, method FTMS 791-321 (100 °C, 30 hours) 5%
- Consistency (ASTM D 1403, $\frac{1}{2}$ scale, 25 °C) after the Roll test (ASTM D 1831, 100 °C) :
- 15 - penetration after 4 hours + 1%
- penetration after 8 hours + 4.1%
- Diameter (ϕ) of the trace left by wear on the 4-ball Shell machine (ASTM D 2266) :
- mean ϕ of the trace left by wear at 50 °C : 1.6 mm
- mean ϕ of the trace left by wear at 120 °C : 1.7 mm
- 20 - Wear load on the 4-ball Shell machine (IP 239 method, spindle speed = 1460 rpm : 600 kg
- Evaporation (ASTM D 972)
- weight loss at 149 °C after 22 hours : 0.01% .

A 100-gram sample of grease was used to fill the lubricating reserve of the ball bearings of a reaction turbine which was driven by carbon tetrachloride vapours. The balls and housing of the bearings were made 25 of AISI 316 steel, the bearing diameter was 30 mm, and the speed of rotation of the turbine was 12,000 rpm.

After a 30-day running of the turbine, the lubrication reserve tank still contained more than 50% of the starting grease. The bearings were removed and their perfect brightness, lack of corrosion and of wear were ascertained.

30

EXAMPLE 3

The same apparatus and the same preparation procedures as described in Example 1 were employed. A grease was formulated starting from 7 kg of polytetrafluoroethylene of the same type as described 35 hereinbefore and from 9.5 l of fluorinated polyether Fomblin Y having a viscosity of 40 cs (20 °C) and additioned with 14 g of a surfactant of formula $\text{CF}_3\text{-}(\text{CF}_2)_3\text{OC}_2\text{F}_4\text{SO}_3\text{K}$.

After mixing in the Z-shaped-arm mixer, the resulting pasty suspension was conveyed to the triple roll mill where, after the third run, a grease having a penetration of 250 mm/10 (ASTM D 1403, $\frac{1}{2}$ scale) was obtained.

40 After a mechanical 10,000-stroke working, the penetration was 270 mm/10, which indicated a high mechanical stability.

The oil separation (FTMS 791-321) at 66 °C after 30 hours was 8%.

The mean diameter of the trace left by wear at 50 °C on the 4-ball Shell machine (ASTM D 2266) was equal to 2.1 mm.

45

EXAMPLE 4

The same apparatus and the same preparation procedures as described in Example 1 were employed.

A grease was formulated starting from 6.5 kg of a polytetrafluoroethylene of the type described hereinbefore and from 9.5 l of fluorinated polyether of formula :

wherein the sum $u + r + s = 3000$, $u/r + s = 0.01$, $r/s = 0.7$, $t \geq 3$; the viscosity of the polyether was 55 29,500 cs / 20 °C.

This perfluoropolyether was prepared according to the process described in Italian Patent Application No. 20270 A/82.

There were additioned 14 g of a surfactant of formula $\text{NaOOCCF}_2\text{O}(\text{C}_2\text{F}_4\text{O})_2(\text{CF}_2\text{O})_2\text{CF}_2\text{COONa}$ and 14 g

of benzimidazole of formula :

- 10 having a molecular weight of 3750 and a p/q ratio of 0.7, synthesized by stoichiometric reaction, at 150 °C in a nitrogen atmosphere, from the corresponding methyl diester and from 3,4-diamino-benzotrifluorine.
After mixing in the arm-mixer, the resulting pasty suspension was passed on the triple roll mill, thus obtaining after the third run a grease having a penetration of 240 mm/10 (ASTM D 1403, $\frac{1}{2}$ scale).
After a mechanical 10,000-stroke working, the penetration was 250 mm/10, which indicated a high
15 mechanical stability. The diameter of the trace left by wear on the Shell 4-ball machine at 50 °C (ASTM D 2268) was equal to 1.1 mm. By carrying out the IP 239 test on a Shell 4-ball machine, a welding load of 650 kg was measured; which proved an excellent wear-resisting behaviour of the grease when used under very high loads.

20 EXAMPLE 5

The same apparatus and the same preparation procedures as described in Example 1 were employed.
The grease was formulated starting from :

- 6.5 kg of polytetrafluoroethylene
25 9.5 l of the polyether indicated in Example 4
14 g of surfactant of formula :

- 30 14 g of phosphine of formula :

- 40 prepared starting from potassium alcoholate, CF₃O(C₃F₆O)₃CF₂CH₂OK, reacted with p.bromobenzylchloride at room temperature, thus obtaining the derivative having a bromobenzene terminal group. The latter was reacted with Li-butyl thus replacing bromine by Li, whereupon the Li-phenyl derivative was lastly reacted with PCl₃.
After mixing in the arm-mixer and milling in the triple roll mill, a grease having a penetration of 250 mm/10
45 (ASTM D 1403, $\frac{1}{2}$ scale) was obtained.
Such grease, subjected to the IP 239 test on a 4-ball Shell machine, exhibited a welding load equal to 800 kg, which revealed an excellent wear-resisting behaviour under very high pressure conditions.

50 EXAMPLE 6

The same apparatus and the same preparation procedures as described in Example 1 were employed. The grease was formulated starting from :

- 6.5 kg of polytetrafluoroethylene
55 9.5 l of the polyether indicated in Example 4
14 g of a surfactant of formula :

16 g of phosphonic derivativ of formula :

having a molecular weight = 4750 and wherein p/q = 0.7, prepared starting from

20 (in its turn obtained from FOCCF2O(CF2CF2O)p(CF2O)q-CF2COF by addition of 2 moles of

in the presence of CsF) by condensation on copper-bromotetrafluorophenyl, fluorination with SF4 in the presence of anhydrous HF, substitution of bromine by lithium and reaction with chloro-bis(trifluoromethyl-phenyl)-phosphine.

30 After mixing in the arm-mixer and milling in the triple roll mill, a grease having a penetration of 250 mm/10 (ASTM D 1403, $\frac{1}{2}$ scale) was obtained.

Such grease exhibited, when subjected to the IP 239 test on a Shell 4-ball machine, a welding load equal to 800 kg, which established a wear-resisting behaviour under conditions of very high pressure.

35 To evaluate the anticorrosive effect and the high stability as well as the chemical inertia of the grease obtained, a sample thereof was treated with oxygen at 232° in the presence of ferrous metal laminae (steel laminae).

Negligible weight variations of the laminae and of the grease were found, in contrast to what happens in the absence of the phosphine derivative.

40 **EXAMPLE 7**

The same apparatus and the same preparation procedures as described in Example 1 were employed.

The grease was formulated starting from :

6.5 kg of polytetrafluoroethylene

45 9.5 l of the polyether indicated in Example 1

14 g of a surfactant of formula :

50 16 g of the phospho-sym.triazine derivative of formula :

5

10

15

20

25

30

55

obtained as in Example 6 and reacted with NH_3 and then with P_2O_5 to obtain the corresponding dinitrile, which, by reaction, at low temperature and at atmospheric pressure, with liquid NH_3 , provided the diamine

which, with an excess of nitrile of formula

yielded imidoylamidine; the latter, with diphenyltrichlorophosphorane $\text{PCl}_3(\text{C}_6\text{H}_5)_2$, provided the product specified above.

- 10 After a mechanical 10,000-stroke working, the penetration was 250 mm/10, which indicated a high mechanical stability. The diameter of the trace left by wear on a Shell 4-ball machine at 50°C (ASTM D 2266) was equal to 1.1 mm.
 By carrying out the IP 239 test on the Shell 4-ball apparatus, a welding load of 650 kg was measured, which indicated an excellent wear-resisting behaviour of the grease under conditions of very high pressure.
- 15 A grease sample was treated with oxygen at 232°C in the presence of ferrous metal (steel) laminae. The volatile product formed (determined on the basis of the weight loss) was in an amount of 1/50 of that by treating a similar grease sample not containing the phosphotriazine compound.
 The lubricating composition obtained according to this Example caused neither rusting of the ferrous metals under mild temperature conditions and at a high moisture degree (ASTM D 1748/70 test), nor rusting under
- 20 high temperature conditions. A similar lubricating grease sample but free from the phosphotriazine compound was subjected to the same tests: both rusting and corrosion of the metal specimens were noticed.

EXAMPLE 8

25

The same apparatus as described in Example 1 was used.

- 7 kg of a polytetrafluoroethylene of the same type as that in Example 1 were introduced into the mixer, were degassed at 50°C under a vacuum of 5.10^{-2} torr, and were added with 9 l of Halocarbon oil 14-25 (Trade Mark of Halocarbon Products Corp., U.S.A.), a low molecular weight polymer of
 30 chlorotrifluoroethylene, having a viscosity of 1,000 cs (100°F), and further added with 14 g of a surfactant of formula

- 35 previously degassed at 50°C under a vacuum of 4.10^{-2} torr. The suspension was homogenized by stirring for 3 hours while the temperature was allowed to decrease to 20°C; a pasty suspension was thus obtained, which was worked on the triple roll mill by passing it 4 times between the rolls, each time for 2 hours, and keeping the rolls in contact with one another under a servofluid pressure of 30 atm. After each run, the following penetration values (ASTM D 1403, $\frac{1}{2}$ scale) were obtained :

40

after the 1st run	242 mm/10
after the 2nd run	238 mm/10
after the 3rd run	236 mm/10
after the 4th run	236 mm/10 .

45

- On a grease sample, which had undergone mechanical 10,000-stroke working, a penetration of 238 (mm/10), corresponding to a high mechanical stability, was measured. On a grease sample, after separation of the oil by means of 1,1,2-trifluorotrichloroethane, the particles of thickening polytetrafluoroethylene were examined under a transmission electron microscope: a particle size distribution ranging from 0.1 to 0.4 microns was determined. The particles exhibited a rounded shape.

Grease samples were subjected to the following measurements :

- Oil separation, method FTMS 791-321 (100°C, 30 hours) 4.1%
- Consistency (ASTM D 1403, $\frac{1}{2}$ scale, 25°C) after the Roll test (ASTM D 1831, 100°C) :
 - penetration after 4 hours + 0.8%
 - penetration after 8 hours + 4%
- Diameter (ϕ) of the trace left by wear on the Shell 4-ball machine (ASTM D 2266) :
 - mean ϕ of the trace left by wear at 50°C 1.5 mm

- mean ϕ of the trace left by wear at 120 °C 1.6 mm
- Wearing load on the Sh II 4-ball machine (IP 239 method, spindle speed = 1460 rpm) : 590 kg.

Claims

5

1. Use of a compound selected from:
 - (a) fluorinated bis-benzimidazoles of the formula:

10

15

wherein R is -F or -CH₃; p and q are integers such as the sum p+q is from 0.1 to 2;
 (b) esters of phosphorous acid with a perfluoroalkoxyalcohol;
 (c) perfluoropolyethers with phosphinic groups at one or both ends;
 (d) perfluoropolyethers with perfluoropolyoxyperfluoro- alkyl-substituted phosphotriazinic groups;

20

as anti-wear additives for a lubricating grease based on polytetrafluoroethylene (PTFE) in the form of fine particles and on a liquid dispersant selected from an oligomer of trifluoro-chloroethylene or from a perfluoropolyether.

25

2. Use according to claim 1, wherein the perfluoropolyether is selected from:

25

- (I) X-O-(C₃F₆O)_m(CF₂O)_n-Y
- (II) A-O-(C₂F₄O)_p(CF₂O)_q-B
- (III) A-O-(C₂F₄O)_r(CF₂O)_s(C_tF_{2t}O)_u-B

wherein:

X and Y are -CF₃ or -C₂F₅; m and n are integers such that the sum m+n is from 10 to 100 and the ratio m/n is from 10 to 50; A and B are -CF₃, -C₂F₅, -CF₂Cl, -CF₂CF₂Cl; p and q are integers such that the sum p+q is from 10 to 200 and the ratio p/q is from 0.1 to 10; r, s, t and u are integers such that the sum r+s+u is from 10 to 3000, the ratio u/(r+s) is from 0.01 to 0.3, the ratio r/s is from 0.1 to 10, t is higher than or equal to 3.

30

3. Use according to claim 2, wherein the perfluoropolyether has a viscosity at 20 °C of from 20 to 4000 cSt when belonging to class (I), of from 50 to 8000 cSt when belonging to class (II), or of from 40 to 30,000 cSt when belonging to class (III).

35

4. Use according to claim 1, wherein the oligomer of trifluorochloroethylene has a viscosity at 20 °C of from 100 to 1,000 cSt.

40

5. Use according to claim 1, wherein the PTFE has a molecular weight of from 500,000 to 1,000,000.

45

6. Use according to anyone of the preceding claims, wherein the lubricating grease is obtainable by a method which comprises:

50

- (A) heating the PTFE particles under vacuum to remove volatile products which may be contained therein;
- (B) soaking and suspending under reduced pressure and at a temperature higher than room temperature the PTFE particles into the dispersing liquid containing a perfluorinated surfactant of the anionic type;
- (C) disaggregating in the so obtained suspension the aggregated particles of PTFE to primary particles.

EP 0 605 403 A2

7. Use according to claim 6, wherein the composition of the resulting lubricating grease is the following, expressed as % by weight with respect to the total weight of the grease: from 15% to 40% of PTFE; from 60% to 85% of dispersing liquid; from 0.1% to 0.4% of surfactant; from 0.2% to 1% of anti-wear additive.

5

8. Use according to claim 6 or 7, wherein the perfluorinated surfactant is selected from:

(A) $\text{CF}_3-(\text{CF}_2)_n-\text{D}$

10 wherein: n is an integer from 2 to 12; D is a group selected from -COOM, -SO₃M, and -O-C₂F₄SO₃M, where M is a cation of Na, K, Ba, Ca;

(B) R-O-(C₃F₆O)_i(C₂F₄O)_k-(CF₂O)_h-Q

15 wherein: R, either like or unlike Q, is selected from -CF₃ and -CF₂COOM, while Q is -CF₂COOM, where M is a cation as defined hereinbefore; i and k are zero or are integers from 1 to 7, provided that, when R is equal to Q, i is zero; h is an integer from 1 to 7; the sum i+k+h is from 2 to 10.
